### Abstract

Biodiesel is a biodegradable fuel made from vegetable oils and animal fats processed by chemical reactions involving catalysts and alcohol. This study aims to determine the occurrence of cooking oil waste produced by residents of DKI Jakarta, to know the average electricity usage of residents in Jakarta, to find out whether the biodiesel produced can meet the electricity needs of every household in DKI Jakarta. The method used in this research is the quantitative method. Primary and secondary data are used to support the paper. Primary data was used from questionnaires distributed to residents of DKI Jakarta, and secondary data used for this paper are literature studies obtained from relevant books, journals, and research. The waste of used cooking oil generated by DKI Jakarta residents is 1,249 L/household/month.

**Keywords:** biodiesel; waste cooking oil; household; electricity

### 1. Introduction

As the time goes by, both the fuel demands and population are increasing. However, the current situation makes us driven to find a new energy source alternative due to the petroleum dwindling to fulfill the population energy demands. Utilizing a new energy source is considered an act to save the ancient energy source, which is petroleum oil. The recent alternative energy that could replace petroleum oil is biodiesel (Raksasat et al., 2021). Biodiesel is a biodegradable fuel that made from vegetable oil and animal fat processed in a chemical reaction involving catalyst and alcohol (Chozhavendhan et al., 2020) By implementing biodiesel as the alternative of ancient energy source, hence, biodiesel is not only a solution for environmental problems but also to economic problems. Because it is an eco-friendly energy source that give benefits to both environment and economic (Singh et al., 2020). The biodiesel feedstock that our group

38 chose is used cooking oil. The used cooking oil mostly came from households, hotels, and  
39 restaurants. Currently, used cooking oil is disposed to an open area or backyards without any  
40 further process to neutralize the waste. So, considering this situation will impact the  
41 environment and save the planet simultaneously, that's why we chose used cooking oil as our  
42 biodiesel feedstock (Rahman et al., 2020).

43 Biodiesel has several advantages over petroleum fuels, which can be produced locally by  
44 utilizing available natural oil/ fat sources. The production process and its use are more  
45 environmentally friendly with low CO, NO, and sulfur emissions and other combustion  
46 compounds and easier to decompose in nature. The use of biodiesel can also reduce soil  
47 pollution and protect the sustainability of water and drinking water sources. Another advantage  
48 of using biodiesel is that there is no need for engine modification. This is because biodiesel has  
49 a cleaning effect on fuel tanks, injectors, and slang, not adding to the greenhouse effect because  
50 the carbon produced is still in the carbon cycle.

51 Furthermore, biodiesel is safer, and its toxicity level is ten times lower than kitchen salt (Mohd  
52 Moiz Khan, Riyaj Uddin Khan, Fahad Zishan Khan, 2013). However, according to (Kelapa et  
53 al., 2009) in addition to these advantages, biodiesel also has drawbacks. This study aims to  
54 determine the occurrence of used cooking oil produced by citizens of DKI Jakarta, determine  
55 the average of electricity usage from DKI Jakarta citizens, and determine whether the biodiesel  
56 produced can meet the electricity needed to households DKI Jakarta.

## 57 **2. Materials and Methods**

58 The method that was applied for this research is the quantitative method. Primary and  
59 secondary data are used to support the paper. Primary data is a source of data received directly  
60 from data collectors. In contrast, secondary data is a source of data received indirectly from data  
61 collectors, such as from other people or available documents. Primary data used for this paper is  
62 the result from a questionnaire distributed to residents of DKI Jakarta as respondents from North  
63 Jakarta, East Jakarta, South Jakarta, West Jakarta, and Central Jakarta. The respondents can fill  
64 out the questionnaire from February 26 until March 6, 2021. Secondary data used for this paper  
65 are literature studies obtained from books, journals, and relevant research.

66 Used cooking oil can be used as a raw material in making biodiesel. The scheme of the  
67 method used for biodiesel production uses previous research carried out in the canteen of the  
68 Jakarta campus (Rahman et al., 2020). However, the content of used cooking oil is high in fatty

69 acids, which requires two times the process of making biodiesel. The first process is esterification  
70 using an acid catalyst and the second process is transesterification using an alkaline catalyst.

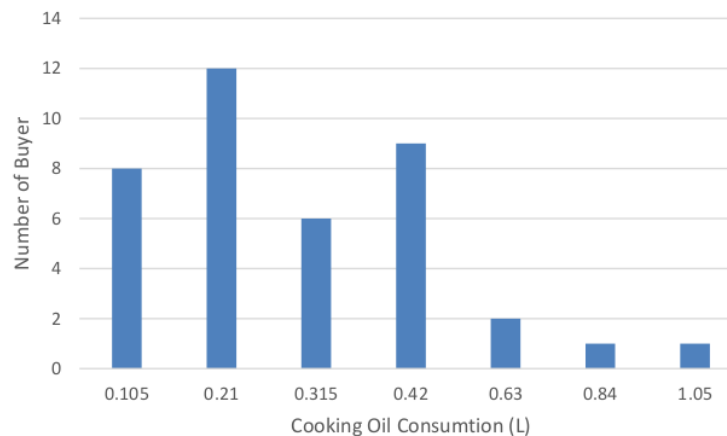

71 **3. Results**

72 Data from the spread of questionnaires about used cooking oil in DKI Jakarta obtained 39  
73 respondents from West, East, North, Central, and South Jakarta. The data is sorted by the  
74 amount of electricity used in one family, the type of oil used, the volume of cooking oil  
75 produced, and the actions taken after the oil is produced. The questionnaire dissemination  
76 period runs from February 26, 2021 – March 6, 2021, using Google Form and disseminated  
77 using social media such as LINE, Instagram, and WhatsApp. From Table 1, a total of 39  
78 Household respondents were obtained. From the 39 households obtained electricity usage data  
79 of 40,693 kWh / month.

80 Table 1. Survey data on electricity usage in DKI Jakarta

Name	Amount	Unit
Total Respondent	39	Households
Total Electricity Used	40.693	kWh/month

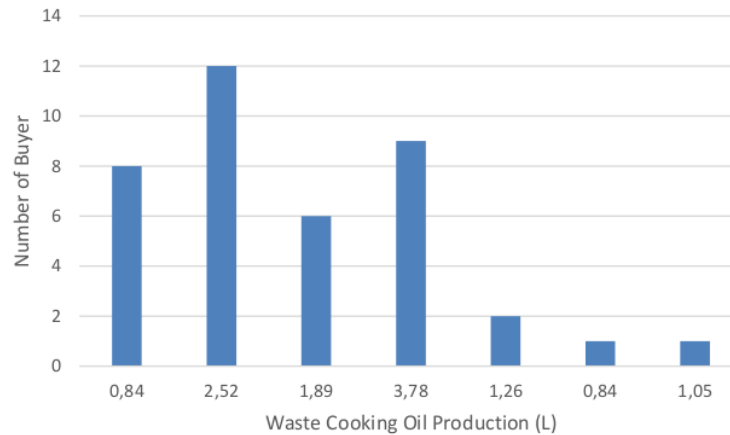

81

83

Figure 1. Total Use of Cooking Oil by Respondents (n=30)

84

85

Figure 2. Total of Waste Cooking Oil by Respondents (n=30)

86

87 From Table 2, the average oil purchase used was 1.249 L/household/month. From table 3.  
88 obtained in the form of oil usage volume of 48.72 L. Percent of used cooking oil produced in  
89 a week from oil purchased is counted below:

90 Percent of used cooking oil produced = (Total of used cooking oil produced / Total of oil  
91 purchased) x 100% (1)

92 = (12.18 L/84.5 L) x 100% = 14.41%

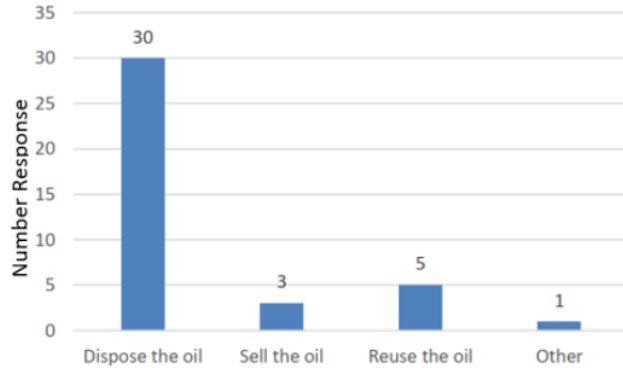

93 From Figure 3. that 56% of respondents of DKI Jakarta use vegetable oil. Then, Figure 4.  
94 obtained the result that most of the respondents of DKI Jakarta have not done anything to the  
95 oil produced using cooking oil. However, some have done reuse of the oil produced

100 **4. Discussion**

101 Used cooking oil is waste from the use of cooking oil originating from households, the food  
102 industry, hotels, and others (Pemerintah Provinsi DKI Jakarta, 2016). Figures 1 and 2 show the  
103 large amount of cooking oil that becomes used cooking oil. This waste needs attention because  
104 it has the potential to affect health and the environment (Gkouskos et al., 2018). Used cooking  
105 oil is a pollutant whose effect is more visible in settlements urban areas. For example, if it is  
106 dumped in a drain, the oil can settle and clog waterways (Chhetri et al., 2008). As can be seen  
107 in Figure 4, most of the used cooking oil is thrown away.

108 In Indonesia, this process has been carried out in Bogor, Padang and Bali (Kharina et al., 2018;  
109 Kurnia & Hadiguna, 2016). The supply chain for the management of used cooking oil is  
110 described in Governor Regulation number 167 of 2016 (Pemerintah Provinsi DKI Jakarta,  
111 2016), but its implementation has not been satisfactory. The poor supply chain's main factor is  
112 the lack of used cooking oil collected (Jachryandestama et al., 2021). However, with good  
113 management, at least it can support zero waste in Jakarta and can provide a circular economy  
114 from used cooking oil.

115 A circular economy is built from a community consumption and production system that  
116 maximizes the services produced, which are interrelated (Korhonen, Nuur, et al., 2018). For  
117 example, materials from nature, the surrounding community, and back to the environment form  
118 a linear relationship and the flow of output in the form of energy produced. This is done by  
119 using a material turnover scheme in the form of waste to produce renewable energy sources in  
120 an economic system oriented towards financial sustainability. A prosperous circular economy  
121 contributes to sustainable development's three dimensions (environment, energy, and  
122 sustainability) (Korhonen, Honkasalo, et al., 2018).

123

124

125 **5. Conclusions**

126 Based on the results and discussions, the value of waste oil produced by the citizens of DKI  
127 Jakarta amounted to 1.249 L/Household/month. For this research, we use two scenarios to treat  
128 used cooking oil produced. The first scenario is the manufacture of 20% biodiesel (B20 and  
129 the second scenario is the manufacture of 100% biodiesel (B100). With the B20 scenario, it  
130 turns out that the electricity needs for the citizens of DKI Jakarta can only meet by 21%.
